The Elimination of the Phase Ambiguity in Projective Methods

Novosibirsk State Technical University

Abstract: The algorithm eliminate the phase ambiguity in projection method of measurements of the surface topography. The method involves the projection of the object arrays with different period. The full difference of stroke are determined on the basis of the analysis of the trajectory of the measured signals.

Keywords: projection; interference; data processing algorithms; unwrapping phase.

I. INTRODUCTION

In a number of practical tasks along with the traditional contact methods of measurement of the surface shape are widely used optical methods. Especially relevant is the application of these methods in such areas, where there is a need for non-invasive method of measurements of the surface shape, and in most cases the measured surface is not fixed on the measuring device.

The main method, which is used in the optical systems for measuring the surface form a three-dimensional objects, is the method of the projection of the bands [1-3].

Field brightness\[I(x, y)\] is of the form
\[I(x, y) = A(x, y) + B(x, y)\cos(\Phi(x, y)),\]
where \(A(x, y)\) is the average brightness, \(B(x, y)\) - amplitude strips, \(\Phi(x, y)\) - complete phase.

\[\Phi(x, y) = \phi(x, y) + 2\pi N(x, y),\]
where \(N(x, y)\) is the number of whole periods \(2\pi\) laid in full optical phase difference (full phase) - \(\Phi(x, y)\), \(\phi(x, y)\) - local phase corresponding to the fractional part of the full phase \(\Phi(x, y)\).

Instead of the phase difference of interfering waves \(\Phi\) it is convenient to introduce into consideration the proportional her value of the difference of the optical (optical path difference) - \(\Lambda\). Complete the difference of the connected with the complete phase as follows:
\[\Lambda = \frac{\Lambda}{2\pi} = \frac{\Lambda}{2\pi}(\phi + 2\pi N) = \delta \Lambda N\]
where \(\delta\) is the local the difference of the corresponding local phase \(\phi\).

The definition of a number of periods is called the elimination of the phase ambiguity [4].

II. PROPOSED METHODS AND SOLUTIONS

The authors proposed a simple algorithm of definition of the full differential phase that does not have these shortcomings. Let us imagine the solution of the system of comparison, as a path in the complex plane. When you change the phase point \((\delta_1, \delta_2)\) will move along the diagonals of the trajectory (see Figure 1).

\[\begin{align*}
\Lambda &= \delta_1 \mod m_1 \\
\Lambda &= \delta_2 \mod m_2
\end{align*}\]

The maximum length of the trajectory \(L_{\text{max}} = m_1 \times m_2 - 1\) sets the dynamic range of an unambiguous definition \(\Lambda\).

In order to find solutions of the system comparisons (4) is used approach based on the application of the extended Euclidean algorithm [6].

Note the shortcomings of this approach. To find the solutions required to fulfill a large number of operations, which, considering the large number of pixels in an image \(10^7-10^8\) and more, leads to unrealistically long time in the calculations. You need to introduce the results of the measurements to an integral mind, which imposes certain restrictions on the dynamic range of measurements. In addition, the algorithm is sensitive to errors of determination of the local phase.

Figure 5. Projection image c period $T = 17$.
(a) - without the shift, (b) - with the grid shift for the period $T/3$, (c) - with the grid shift for the period $2T/3$.
Figure 6. Projection image c period $T = 23$. (a) - without the shift, (b) - with the grid shift for the period $T/3$, c) - with the grid shift for the period $2T/3$.

Figure 7. Local differential of path ((a) - period $T = 17$, (b) - period $T = 23$)

Figure 8 shows the trajectory of local differences.

Figure 8. The trajectory of local differences

Complete the difference of the calculated according to the formula

$$\Delta x = \Lambda_x + \delta_1$$  \hspace{1cm} (7)

if point is located on the bottom diagonal and according to the formula

$$\Delta x = \Lambda_x + \delta_2$$  \hspace{1cm} (8)

if point is located at the top of the diagonal.
III. EXPERIMENTS

For practical verification of the proposed technology was used projection system, consisting of the projector (800x600 pixels) and the camera (1600x1200 pixels). The size of the projection image was 2x2 meters. The grating grooves were perpendicular conquerors to the plane, which passed through optical axes of illumination system and recording optical system. The optical axes of recording and illumination systems intersected in one point in the object’s area. The angle between axes of recording and illumination systems was 10°. The distance between the object’s plane and the target’s plane was 3 m. The arrangement fastened to unmovable platform. The figures of 5.6 shows the projection of the image, obtained with various shifts projection grid for the (0, \( T/3 \), 2\( T/3 \)), where \( T \) - the period of the grid \( T = 17 \) (Figure 5) and \( T = 23 \) (Figure 6). Figure 7 shows the local difference of course, the corresponding periods of the projection grids \( T = 17 \) (Figure 7a) and \( T = 23 \) (Figure 7b).

Figure 9 shows the result of calculating the difference of the progress on the proposed algorithm.

IV. CONCLUSION

We presented a simple algorithm elimination phase ambiguity, which does not require the submission of the initial data in the general form. The algorithm requires a small amount of computation and resistant to measurement errors local phases.
